

Linear Models and SVMs

Optimization for Machine Learning — Exercise 02

Monday 24th April, 2023

Part I: Theory

I.1. Linear model example

Exercise I.1 (Polynomial Curve Fitting). Given a set of points and their targets $\{x_i, t_i\}_{i=1}^N$ so that for $i \in [N]$, $x_i \in \mathbb{R}$ and $t_i \in \mathbb{R}$, the *curve fitting problem* is loosely defined as finding a function $f: \mathbb{R} \rightarrow \mathbb{R}$ such that $f(x_i) \approx t_i$ for all $i \in [N]$.

In order to find such a function, we restrict ourselves to a set of parametrized functions \mathcal{F} : each function can be parametrized with a vector $\mathbf{w} \in \mathbb{R}^D$.

To quantify the problem further, in this exercise, we limit ourselves to *polynomial functions* of degree D for the set \mathcal{F} , and can therefore write

$$f(x, \mathbf{w}) = w_0 + w_1x + \dots + w_Dx^D = \sum_{k=0}^D w_kx^k \quad (1)$$

Notice how f is *linear* in \mathbf{w} , the parameter. Such model is called a *linear model*.

With N samples, we defined the loss (or error, or energy) of our parameter as the point-wise square distance between its estimation and the target:

$$E(\mathbf{w}) = \frac{1}{2} \sum_{i=1}^N (f(x_i, \mathbf{w}) - t_i)^2 \quad (2)$$

1. Is the function E convex in \mathbf{w} ? How to find the optimal parameter \mathbf{w}^* at which the loss is minimum?

2. Compute the gradient $\nabla_{\mathbf{w}} E(\mathbf{w}) = \begin{pmatrix} \partial_{w_0} E(\mathbf{w}) \\ \vdots \\ \partial_{w_D} E(\mathbf{w}) \end{pmatrix} \in \mathbb{R}^D$.

3. Show that the optimal parameter \mathbf{w}^* satisfies the following system of equation:

$$\sum_{j=0}^D A_{ij} w_j = T_i,$$

where

$$A_{ij} = \sum_{k=1}^N (x_k)^{i+j}, \quad T_i = \sum_{k=1}^N (x_k)^i t_k. \quad (3)$$

4. Is such a system of equation solvable? When / not?

It is usual the add a *regularizer* to the objective, penalizing “complex” models, helping to select one when the solutions are plenty. One of the most common regularizer is the parameter squared-norm: with a *penalizer weight* $\lambda \in \mathbb{R}_+$, the Equation (2) is modified to give

$$E_\lambda(\mathbf{w}) = E(\mathbf{w}) + \frac{\lambda}{2} \|\mathbf{w}\|^2 = \frac{1}{2} \sum_{i=1}^N (f(x_i, \mathbf{w}) - t_i)^2 + \frac{\lambda}{2} \|\mathbf{w}\|^2. \quad (4)$$

5. What is the role of λ ?

6. Is E_λ convex?

7. Show that the optimal weight w^* is now found by solving

$$\sum_{ij} (A_{ij} + \lambda) w_j = T_i,$$

with A_{ij} and T_i defined as in Equation (3).

Matrix expression It is sometimes preferable to deal with vector and matrices, rather than scalar expressions. When the model is linear in \mathbf{w} , it is possible to express it as a *linear product* between a matrix and a vector. The expression in Equation (1) can be thought as a dot product

between w and the vector of powers of x , that define as $\phi(x) := \begin{pmatrix} 1 \\ x \\ x^2 \\ \vdots \\ x^D \end{pmatrix}$, so that

$$f(x, \mathbf{w}) = \mathbf{w}^\top \phi(x).$$

Stacking all the N examples in a matrix, and denoting $\phi_i := \phi(x_i)$, we define

$$\Phi := \begin{pmatrix} | & | & \cdots & | \\ \phi_1 & \phi_2 & \cdots & \phi_N \\ | & | & & | \end{pmatrix} \in \mathbb{R}^{D \times N}$$

and can therefore compute the model *on the whole dataset* in one expression: $\mathbf{y}(\mathbf{w}) = \Phi^\top \mathbf{w} \in \mathbb{R}^N$. Each entry i of \mathbf{y} corresponds to a different sample x_i . Then, stacking the targets into a vector $\mathbf{t} \in \mathbb{R}^N$, the error function (2) can equivalently written as

$$E(\mathbf{w}) = \frac{1}{2} \|\mathbf{y}(\mathbf{w}) - \mathbf{t}\|^2,$$

and the regularized error as

$$E_\lambda(\mathbf{w}) = \frac{1}{2} \|\mathbf{y}(\mathbf{w}) - \mathbf{t}\|^2 + \frac{\lambda}{2} \|\mathbf{w}\|^2$$

8. Show that $\nabla E_\lambda(\mathbf{w}) = \Phi(\Phi^\top \mathbf{w} - \mathbf{t}) + \lambda \mathbf{w}$, so that \mathbf{w}^* solves the linear equation

$$(\Phi\Phi^\top + \lambda I_D) \mathbf{w}^* = \Phi \mathbf{t}.$$

I.2. Support Vector Machines (SVM)

In order to implement a first SVM algorithm, we will need the notion of *subgradient* we give next.

I.2.1. Subgradients

When a convex loss function $E: \mathbb{R}^d \rightarrow \mathbb{R}$ is not differentiable, its *subgradient* can be used. It is defined as the set, for $x \in \mathbb{R}^d$,

$$\partial E(x) = \{g \in \mathbb{R}^d \mid \forall y \in \mathbb{R}^d, E(y) \geq E(x) + \langle g, y - x \rangle\}.$$

If E is differentiable at x , then $\partial E(x) = \{\nabla E(x)\}$.

For instance, for $E: \mathbb{R} \rightarrow \mathbb{R}$, $x \mapsto E(x) = |x|$, E is differentiable at any $x \neq 0$, with gradient -1 on $(-\infty, 0)$ and 1 on $(0, +\infty)$.

At $x = 0$, we compute, for any $y \in \mathbb{R}$ and $g \in \mathbb{R}$:

$$\begin{aligned} E(y) \geq E(0) + \langle g, y - 0 \rangle &\iff |y| \geq \langle g, y \rangle \\ &\iff |y| \geq gy \end{aligned}$$

This condition has to be true for *any* $y \in \mathbb{R}$. This is only true when $g \in [-1, 1]$. Therefore,

$$\partial E(x) = \begin{cases} \{-1\} & \text{if } x < 0 \\ [-1, 1] & \text{if } x = 0 \\ \{1\} & \text{if } x > 0 \end{cases}$$

Geometrically, this can be interpreted as having, for the absolute value at the origin, any lines with slope between -1 and 1 lower-bounding the graph of the function.

Exercise I.2. Let $E: \mathbb{R} \rightarrow \mathbb{R}$, $x \mapsto E(x) = \max(0, 1 - x)$.

1. Where is E differentiable?

2. Show that $\partial E(x) = \begin{cases} \{0\} & \text{if } x < 1 \\ [0, 1] & \text{if } x = 1 \\ \{1\} & \text{if } x > 1 \end{cases}$

I.2.2. SVM problem

Now, the SVM problem can be presented. We will discuss the (pure) linear case.

Support Vector Machines solve a binary classification task. Given N couples samples / targets $\{x_i, t_i\}_{i \in [N]}$, with $x_i \in \mathbb{R}^d$ and $t_i \in \{-1, 1\}$ for each $i \in [N]$, the goal is to classify the samples, i.e. find a **hyperplane that separates them**, with positive samples on one side of the hyperplane and the negative on the other. We assume that such an hyperplane exists (the samples are said to be *linearly separable*).

A hyperplane in \mathbb{R}^d is represented with a vector $w \in \mathbb{R}^d$ and a *bias* $b \in \mathbb{R}$ with the equation

$$y(x) = \langle w, x \rangle + b.$$

This equation splits \mathbb{R}^d into three regions:

- points such that $y(x) > 0$,
- points such that $y(x) = 0$ (the hyperplane itself),
- points such that $y(x) < 0$.

Therefore, we would like to find an hyperplane such that the samples x_i that have a positive target $t_i = 1$ all lie on the side of the hyperplane where $y(x) > 0$, and reciprocally all samples x_i such that $t_i = -1$ should be on the side where $y(x) < 0$.

Therefore, the product $t_i y(x_i)$ should always be positive. Based on that, the loss we defined is

$$E(w) = \sum_{i=1}^N \max(0, 1 - t_i y_i) = \sum_{i=1}^N \max(0, 1 - t_i (\langle w, x_i \rangle + b)) \quad (1)$$

- Exercise I.3.**
1. Is the loss E convex? Differentiable?
 2. Compute the subgradient of the loss E at w .
 3. What should be the (sub-) gradient descent algorithm to minimize E ?

Part II: Programming

Exercise II.1. Model fitting This exercise implements some results found in Exercise I.1.

1. **Generation of the target.** In this toy example, we generate the N points ourselves. The true target t_i will be sinusoidal, with some noise, i.e. $t_i = \sin(2\pi x_i) + \varepsilon$, where $\varepsilon \sim \mathcal{N}(0, \sigma^2)$. The different scales (for σ, x_i) are given as $\sigma = 0.1$, and $x_i \sim \mathcal{U}([0, 1])$, uniform distribution on the segment $[0, 1]$.

The generation of the data is performed by the function `gen_sin_data` in the file `ex02/Utils.py`.

2. Implement the parametrization function (1) as $f(x, w)$, where the dimensions D is implied by the size of w .
3. Implement the error function E defined in (2), and its gradient $\nabla E(w)$.
4. Find w^* , either by
 - a) gradient descent; or
 - b) solving the linear system of equations (3).

Exercise II.2 (SVM). This exercise implements some material from Exercise I.3. The data is generated with the helper function `gen_binary_data` in `ex02/utils.py`. The dimension is set to $d = 2$ in order to visualize the result at the end. The generation simply draws some random points on the plane, draws an hyperplane, and classify the points depending on the sign of $w^\top x + b$. Therefore, the training data is linearly separable.

1. Implement the loss from (1).
2. Implement the (sub-) gradient algorithm derived in I.3.3
3. Visualize the solution found by the algorithm. What happens if the data is not linearly separable?
